NOTICE

This manual was written by the Yamaha Motor Company primarily for use by Yamaha dealers and their qualified mechanics. It is not possible to put an entire mechanic's education into one manual, so it is assumed that persons using this book to perform maintenance and repairs on Yamaha motorcycles have a basic understanding of the mechanical concepts and procedures inherent to motorcycle repair technology. Without such knowledge, attempted repairs or service to this model may render it unfit to use and/or unsafe.

This model has been designed and manufactured to perform within certain specification in regard to performance and emissions. Proper service with the correct tools is necessary to ensure that the motorcycle will operate as designed. If there is any question about a service procedure, it is imperative that you contact a Yamaha dealer for any service information changes that apply to this model. This policy is intended to provide the customer with the most satisfaction from his motorcycle and to conform with federal environmental quality objectives.

Yamaha Motor Company, Ltd. is continually striving to improve all models manufactured by Yamaha. Modifications and significant changes in specifications or procedures will be forwarded to all Authorized Yamaha dealers and will, where applicable, appear in future editions of this manual.

NOTE:
This Service Manual contains information regarding periodic maintenance to the emission control system for the CV80K. Please read this material carefully.

Particularly important information is distinguished in this manual by the following notations:

NOTE: A NOTE provides key information to make procedures easier or clearer.

CAUTION: A CAUTION indicates special procedures that must be followed to avoid damage to the motorcycle.

NEW FEATURES

ELECTRIC FUEL METER

The fuel sensor unit incorporates a variable resistor, and the fuel meter has a movable 2-pole magnet in it. The sensor unit is provided with a float through the float lever. As the fuel level changes, the float also moves up and down. The movement of the float changes the resistance of the sensor and thus changes electrical current flowing in the sensor unit. As the current changes, it moves the magnet connected to the fuel meter needle, thus indicating the fuel level. This new type fuel meter always indicates the remaining amount of the fuel even after the main switch is turned off.

Fuel level is low
When the float is low, the variable resistor increases its resistance, and thus the current flows more to coil (Lf) than to coil (Le). That is, the magnetic flux on the (Lf) side is greater than on the (Le) side so that the magnet turns to the left and as a result, the meter needle moves toward (E).

OPERATION

Fuel level is high
When the float is high, the variable resistor decreases its resistance, and thus the current flows more to coil (Le) than to coil (Lf). That is, the magnetic flux on the (Le) side is greater than on the (Lf) side so that the magnet turns to the right and as a result, the meter needle moves toward (F).
V-BELT DRIVE SYSTEM

No gear shifting is required because the reduction ratio automatically changes with the engine speed. Stable climbing ability and smooth acceleration are ensured, independent of the rider's driving technique.

OPERATION

Starting off
The V-belt is positioned near the center of the primary sheave and near the perimeter of the secondary sheave at the same time. With the V-belt in this position, the reduction ratio is maximum so that full engine torque can be transmitted to the rear wheel. (Greater torque can be transmitted.)

Stall r/min: 3,500

At medium speeds
As the engine speed increases, the sheave weights are thrown outward by centrifugal force, and the weights force the movable sheave inward. This means that on the primary sheave, the V-belt is forced toward the perimeter of the primary sheave and on the secondary sheave, the belt moves toward the center of the sheave. In other words, the reduction ratio decreases slowly and thus the secondary sheave speed increases.
At high speeds
As the engine speed increases further, the sheave weights are also thrown further outward. This means that on the primary sheave, the V-belt is further forced toward the perimeter and on the secondary sheave, the V-belt is nearest the center of the sheave. With the V-belt in this position, the reduction ratio is minimum.

Effect
For instance, the rider opens the throttle when approaching a slope and because of the construction and operation of the helical splines provided for the secondary sheave shaft, the movable sheave moves toward the fixed sheave. This causes the V-belt to move toward the perimeter, and higher reduction ratio and greater torque required for climbing up the slope can be obtained.

HELICAL SPLINES
Operation and construction
Engine torque is transmitted to the secondary sheave through the V-belt. The torque transmitted to movable sheave is changed to a thrust force that pushes the movable sheave toward the fixed sheave because of the helical splines. As a result, the V-belt is moved toward the perimeter, thus increasing the reduction ratio.
"VIBELESS" LINK ENGINE MOUNTING

This engine mounting system effectively shuts off the unpleasant engine vibration to the frame so that superb riding comfort can be ensured.

The engine vibrates centering on the "P" point and the vibration is effectively damped out by the rubber dampers and springs.

ENERGY-SAVING S.E. CARBURETOR

Unlike a conventional carburetor, the venturi has a cross-section shown to the right. The size of the throttle opening at full-throttle is almost the same as a round-type venturi, but at partial throttle the opening is smaller than in the conventional type. That is, fuel can be economized and at the same time, the engine can pick up speed smoothly. Along with the variable speed V-belt drive, the carburetor is designed with importance on fuel economy.
AUTO-CHOKE
The CV8OK employs an auto-choke system that allows even the beginner a quick, easy start. That is, the operation of the choke lever is unnecessary.

This system is made up of the following three components; B. V. S. valve, fuel cock, and carburetor.

| B. V. S. valve | Fuel cock | Carburetor |

Construction
This system has two bimetals which deflect when they are subjected to a change in temperature. In other words, the two thermostats open and close the vacuum passage depending on the cylinder head temperature, and thereby the supply of mixture from the starter plunger chamber to the combustion chamber can be stopped or kept on.

Bimetal
This is a strip of two metals having different temperature coefficients so arranged that the strip deflects due to a change in temperature.

| Operating temperature | 44°C or below | 58°C ± 7°C |
| Return temperature    | 34°C ± 2°C    | 58°C ± 7°C  |

Elongation caused by heat
1. High temperature bimetal
2. Low temperature bimetal
3. Nozzle A
4. Nozzle C
5. Bypass nozzle B
OPERATION

Cold engine

When the starter switch is pushed, the crankshaft begins to turn and thus a partial vacuum is produced in the crankcase. As the vacuum is created, the fuel cock valve is opened, thus allowing gasoline into the carburetor.

As the engine is cold, the low temperature bimetal (valve C) is closed but the high temperature bimetal (valve B) is open. In this case, the vacuum produced in the carburetor does not actuate the choke valve; that is, the choke valve is kept open so that the proper mixture required to start the engine is supplied.

Slightly warm engine

When the engine warms up, the low temperature bimetal (valve B) opens slightly and thus a partial vacuum is produced in the carburetor vacuum chamber.

Therefore, the diaphragm is moved toward the vacuum side and pushes the choke valve downward.
Warm engine

As the engine warms up completely, the low temperature bimetal (valve C) opens, but the high temperature (valve B) is closed.

Restarting

When the engine is still warm, the fuel cock valve is kept closed and thus, the vacuum is held in the vacuum chamber. As a result, the choke valve is pushed downward.

As the engine cools down slowly to about 58° ± 7°C or less, the high temperature bimetal (valve B) opens to allow atmospheric pressure into the bypass and as a result, the choke valve is open.
IGNITION CONTROL SYSTEM

The CV80K distinctly indicates START and RUN on the main switch. The electric engine speed control unit prevents the motorcycle from lurching forward due to the rider's unskillful operation.

**WARNING:**

Never start the engine or let it run for any length of time in a closed area. The exhaust fumes are poisonous and can cause death within a short time. Always operate the motorcycle in an area with adequate ventilation.

**START:** The start indicator light will come on in this position. The engine can be started, but the engine speed can not be increased by opening the throttle.

**RUN:** The motorcycle can be run by operating the throttle. The engine can not be started in this position.

**Operation**

1. When the kick starter is kicked or the starter button is depressed, the flywheel magneto turns and the charge coil generates a voltage of 150 to 350 volts which is stored in the condenser in the CDI unit. When a trigger voltage from the pulser coil turns on the SCR1 (silicon-controlled rectifier), the electricity stored in the condenser is discharged to the primary winding of the ignition coil. This induces a high voltage surge in the secondary winding and produces a spark across the spark plug gap.

2. When the kick starter is kicked or the starter button is depressed with the key opened, the engine speed will increase slowly. But before the engine reaches the speed where the clutch engages, a trigger voltage from the pulser coil turns on the zener diode (ZD) which turns on SCR2. As a result, the voltage from the charge coil is not supplied to the CDI unit; thus no spark is produced at the spark plug. As the engine speed decreases, both ZD and SCR2 turn off, and the engine runs normally by utilizing the CDI circuit. By alternating the operation specified in 1 and 2 above, the engine speed is controlled to $2,300 \pm 300$ r/min.

3. When the main switch key is turned from START to RUN, the engine speed control unit will not function, and the engine operates through the CDI circuit. The engine speed will increase in response to the throttle opening so that you can start off. When the main switch key is turned from RUN to START, the engine speed control unit will function to control the engine speed. That is, the engine is placed under the condition described in 2 above.
4. When the kick pedal is kicked or the starter button is depressed with the main switch turned to RUN, the engine speed control unit turns on, and the voltage generated by the charge coil flows through SCR2 to ground. This means that no spark is produced and thus the engine will not start.

PERIODIC INSPECTIONS AND ADJUSTMENTS

INTRODUCTION

This chapter includes all information necessary to perform recommended inspection and adjustments. These preventative maintenance procedures, if followed, will insure more reliable vehicle operation and a longer service life. The need for costly overhaul work will be greatly reduced. This information applies not only to vehicles already in service, but also to new vehicles that are being prepared for sale. Any service technician performing preparation work should be familiar with this entire chapter.

MAINTENANCE INTERVALS CHARTS

Proper periodic maintenance is important. Especially important are the maintenance services related to emissions control. These controls not only function to ensure cleaner air but are also vital to proper engine operation and maximum performance. In the following maintenance tables, the services related to emissions control are grouped separately.

### ANTICIPATED MAINTENANCE

The maintenance items in this table are set apart from the regular periodic maintenance items because of their anticipated need of irregular service intervals. The service interval is dependent upon variable factors such as the severity of use, operating conditions, etc. Therefore, perform this maintenance when the described symptoms warrant it.

<tr>
<td>3</td>
<td>Piston</td>
<td>If the piston rattles, the vehicle becomes hard to start, appears to be lacking power, or becomes inoperative, repair as follows: replace the piston and piston rings, clean, hone, or replace the cylinder. These symptoms are anticipated to occur mainly below 500 km (300 mi).</td>
</tr>
</tbody>
</table>
1. Spark plug
   a. Symptoms — If the spark plug becomes wet with fuel or oil, or receives an accumulation of carbon, the spark plug will become electrically shorted and ineffective. As a result, engine misfiring may occur, possibly the engine may suddenly stop, and restarting will be impossible. These symptoms are anticipated to occur at about 3,000 km (2,000 mi).
   b. Maintenance criterion — If above mentioned symptoms are noticed, remove the spark plug and inspect the electrode for carbon bridging and/or oily electrode condition.
   c. Maintenance — After inspection, replace plug if necessary.

2. Decarbonization
   a. Symptoms — If a vehicle is driven habitually at low speed, the engine runs cold and thus carbon tends to build up on the cylinder exhaust port, cylinder head, piston head, exhaust passage, in the exhaust pipe, and in the silencer. With sufficient carbon deposits the exhaust passages become clogged and restricts the passage of exhaust gas. Eventually the engine will demonstrate poor performance, poor acceleration (20 to 30% down from original), afterburning, or after running.
   Sufficient carbon accumulation to justify decarbonization is anticipated to occur between 5,000 (3,100 mi) to 10,000 (6,200 mi) of operation.
   b. Maintenance criterion — If any of the symptoms above are noticed, following procedures should be used;
   1) Check fuel flow.
   2) Check spark plug for color and carbon build-up. (In the case of heavy carbon build-up, spark plug shows black color and/or the carbon build-up evident.)
   c. Maintenance — After this inspection, if decarbonization is deemed necessary, decarbonate the piston crown, exhaust port, cylinder head and exhaust passage of exhaust system by disassembling these components and carefully scraping the accumulated carbon with a round scraper.

3. Piston
   a. Symptoms — If the engine develops a rattling piston noise, is difficult to start, provides markedly reduced performance (20% or more), and/or causes a sudden engine stoppage, the piston may be worn excessively. This may be the result of a number of conditions of improper carburetion, inadequate or improper lubrication and/or improper ignition timing. Such conditions can result in overheating and piston wear. These symptoms are anticipated to occur below 500 km (300 mi).
   b. Maintenance criterion — If any of the above mentioned symptoms are noticed, following procedures should be used;
   1) Check fuel flow.
   2) Check for kick cranking resistance. (If the piston is worn, the resistance of the kick crank will be unusually heavy or unusually light.)
   3) Check the spark plug for unusual color or deposit. (If piston is worn, the spark plug may show a bright metallic color or deposit on the spark plug insulator.)
   c. Maintenance — If an inspection reveals damage to the cylinder, bore or replace the cylinder, and replace the piston and piston rings. Make sure proper piston clearance is maintained.
SIDE COVER – INSTALLATION AND REMOVAL

When checking parts (e.g., periodic inspection) or charging the battery, side cover 2 and 3 must be removed. To remove, follow the following procedure:

Removing side covers 2 and 3.
1. Remove the damper clamps positioned between side covers 2 and 3.

NOTE:
- To release the front damper clamp, push it to the front. (Don’t push it sideways, or the hook could be damaged.)
- Avoid prying the clamp out using a slotted-head screwdriver, or the side cover may be scratched.

2. Loosen the knob and unhook the side covers.
Installing side covers 2 and 3.
1. Fit the grommet (inside the side cover) at the rear and install the side covers.
2. Slightly lift up the mat 1 at the rear of the foot board and set the front of the covers, and put together the front parts of the covers.
3. Put together side covers 2 and 3. (Fit the projection on side cover 2 to the recess in side cover 3.)
4. Insert the front and rear damper clamps and tighten the knob.

NOTE:
When installing or removing the side covers, be sure to hold the areas marked with a circle (⊙).

Installing side cover 4
1. Turn in both ends of mat 1.
2. Bring the cut in the footrest board to align with the projection of side cover 4.
3. Tighten side cover knob 1.
4. Align the projection on mat 1 with the hole in the footrest board, and install side cover 4.

ENGINE
CARBURETOR

Throttle cable play
Check the free play of the throttle grip at its flange.

Throttle grip free play:
3 ~ 7 mm (0.12 ~ 0.28 in)

If play exceeds the above value, loosen the lock nut and adjust the play by turning the adjuster.

NOTE:
- After adjusting, turn the handlebars to right and left and make sure that the engine idling does not run faster.
- Tighten the lock nut completely.
Idle-speed adjustment
1. Remove side cover 4.

2. Start the engine and warm it up before setting idle speed.

NOTE:
A warm engine is defined as one which had been operated for about 3 minutes at 3,000 r/min with no load.

3. Set the idle speed to specified setting by turning the throttle stop screw in or out with the motorcycle in the upright position.

   Idle speed: 1,350 ~ 1,500 r/min

4. By turning the throttle grip, make sure the engine runs stably.

OIL PUMP

Oil pump wire free play – checking and adjustment
1. Remove side cover 4.
2. Remove the grommet from the oil pump cover.

3. Adjust throttle cable 2 that it has a play of 1 mm on the carburetor side.

4. While keeping a play of 1 mm on the carburetor side, bring the match mark on the oil pump to align.

   If it is impossible to produce a play of 1 mm, loosen the lock nut and make the necessary adjustment by turning the adjuster.
5. If the match mark is not aligned, loosen the pump cable lock nut and adjust by turning the adjuster.

NOTE: After adjusting, be sure to tighten the lock nut completely.

Air bleeding
The oil pump must be bled after the oil pipe or oil pump is reinstalled.
1. Remove the oil pump cover.
2. Remove the bleeder bolt.
3. When the bleeder bolt is removed, oil containing air bubbles flows out. Let the oil flow out until air bubbles completely disappear, and reinstall the bleeder bolt.

NOTE:
- Place a rag or oil can under the engine.
- Add the Autolube oil to the oil tank before bleeding.
- Thoroughly clean the engine exterior of oil.

ENGINE OIL (AUTOLUBE OIL)
We recommended Yamalube 2-cycle oil. If for any reason you should use another type, use air cooled 2-stroke engine oil or a 2-cycle engine oil labeled "BIA certified for service TCW".

TRANSMISSION OIL REPLACEMENT
Replacement intervals
Replace the gear oil according to the following chart.

Recommended oil
Yamalube 4-cycle oil or SAE 10W30 type SE motor oil or GL gear oil

Draining the oil
1. Remove the drain bolt on the bottom of the gear case and drain the oil.
2. After draining, clean the drain bolt, install the bolt, and tighten to specification.

Drain bolt tightening bolt: 20 Nm (2.0 m·kg, 14.5 ft·lb)
Refilling with oil

TIRES

WARNING:

1. Proper loading of your motorcycle is important for the handling, braking, and other performance and safety characteristics of your motorcycle. NEVER OVERLOAD YOUR MOTORCYCLE. Make sure the total weight of the accessories, etc. do not exceed the maximum load limits. Operation of an overloaded motorcycle could cause tire damage, an accident, and injury.

2. Improper tire pressures greatly affect tire life and handling. Check tire pressures prior to each trip and adjust properly if necessary.

If tire pressures are too high, shocks from the road will not be damped and will be carried to the frame and handlebars, thus adversely affecting riding comfort. In addition, motorcycle stability will be poor when making a turn.

If tire pressures are too low, tires will be deformed greatly, thus shortening tire life. When braking the wheels, tires could slip over wheel rims and tire tubes could broken. When turning the corner or the curve, the motorcycle could easily turn over.

Tire pressure
When checking tire pressure, the tire must be cold. Using an air gauge, measure tire pressure.

b. Hold both ends of the handle cover cap, and remove the cap by pushing it diagonally to the rear.

**HANDLEBARS**

**Checking**

1. Place the motorcycle on the centerstand, raise the front wheel off the ground, and check that the handlebars turn smoothly and have no excessive play.

2. If the handlebars are stiff to turn or have excessive play, check the tightness of the steering fitting nut and handlebar mounting bolt.

1. Steering nut wrench
3. Tighten the steering fitting nut and handlebar mounting bolt.

Tightening torque:

ELECTRICAL

BATTERY

Checking the battery fluid level
1. Remove side cover 2.
2. Check to see that the fluid level is between the upper and lower level lines.

1. Upper level 2. Lower level

If the fluid level is lower than the lower line, add distilled water.

NOTE:
To check the level, use the center stand on level place.

Checking the specific gravity of the battery fluid
1. Disconnect both positive and negative wires of the battery.
2. Remove the battery case mounting screws, and remove the battery.

Take reading at eye level

Specific gravity: 1.280 at 20°C (68°F)

If the specific gravity measured is less than the above figure, recharge the battery.
Recharging

Charge the battery at the 10-hour rate (at an amperage of 1/10 of the battery capacity) until the specific gravity reaches the specified value.

**CAUTION:**

- Keep off fire.
- Select a well-ventilated place.
- Remove the battery caps.
- Avoid quick charging, or the battery could be ruined.
- Be sure to use the charger switch to turn on and off.
- Don't allow the fluid temperature to rise to higher than 45°C (113°F).
- Replace the battery, if it has sediments.
- Replace the battery, if it shows a sign of sulfation.
- After charging, install the caps and wash the battery with water.

**NOTE:**

- If the breather pipe is improperly connected or routed, the battery fluid may spill on tires, wheels, or case cover, thus causing corrosion.
- A broken or clogged breather pipe may cause damage to the battery.

- The breather pipe has a slit at a point 30 mm (1.2 in) from its end on the battery side. Be careful not to connect it the other way round.
- Be careful not to touch the slit area because it is often wet with the battery fluid.

**CAUTION:**

TAKE SPECIAL CARE WHEN HANDLING THE BATTERY.

Be sure to follow these instructions. The battery emits combustible gas, so if it is handled improperly, explosion could occur, causing injuries.

- Keep away from fire-spark. Never smoke or produce a near the battery when charging.
- The battery should be charged in a well-ventilated area, or explosion could occur. Battery electrolyte is poisonous and dangerous, causing severe burns, etc. It contains sulfuric acid. Avoid contact with skin, eyes or clothing.

Antidote:
EXTERNAL — Flush with water.
INTERNAL — Drink large quantities of water or milk. Follow with milk of magnesia, beaten egg or vegetable oil. Call physician immediately.

Eyes: Flush with water for 15 minutes and get prompt medical attention. Batteries produce explosive gases. Keep sparks, flame, cigarettes, etc. away. Ventilate when charging or using in closed space. Always shield eyes when working near batteries. KEEP OUT OF REACH OF CHILDREN.
SPARK PLUG

Checking

1. After a run of initial 1,000 km (600 mi), check the discoloration of the spark plug and clean it.
2. Remove the spark plug cap and remove the plug.

If the spark plug has heavy carbon deposits, clean using a plug cleaner or wire brush.

3. Whenever the spark plug is replaced or cleaned, measure the plug gap, and if incorrect, readjust the plug gap.
4. Replace the spark plug when the machine has travelled the specified distance. When replacing the spark plug, always use the proper type.

Replacement limit:
Initial 4,000 km (2,500 mi) and thereafter every 3,000 km (2,000 mi)

Spark plug gap
Check the plug gap.

Spark plug gap:
0.6 ~ 0.7 mm (0.024 ~ 0.028 in)

Adjust the plug gap by bending in or out the side electrode.

Standard spark plug  BP7HS (NGK)

Tightening
1. First screw it in with your fingers until tight, and then tighten it to specification using a plug wrench.
Tightening torque:
20 Nm (2.0 m·kg, 14 ft·lb)

NOTE:
Don't tighten the spark plug using a plug wrench at the first time. (Threads of the spark plug hole in the cylinder head could be damaged.)

2. Install the plug cap and install side cover 4.

7. Take care so that the battery fluid does not spill on your clothes or the motorcycle.

**CAUTION:**

Take the following precautions.
The battery emits inflammable gases.
Exercise special care, or explosion could occur.
- Keep away from fire, cigarettes, electric sparks, etc.
- When charging the battery, select a well-ventilated place. Never attempt to charge the battery in a closed place.
- Take special care so that the battery fluid (diluted sulfuric acid) does not splash to your skin, eyes or clothed.
  You may be burned or injured in the eyes.
First aid:
- Should the battery fluid splash to your skin or clothes, wash it out with plenty of water.
- Should it splash to your eye, wash it away with water immediately and go to a doctor.

6. Cylinder head mounting nuts.

7. Cylinder head.

Checking
Using a straight edge and thickness gauge, check the cylinder head for warpage.

Max. warpage: 0.02 mm (0.0008 in)

If warpage exceeds the above limit, resurface or replace the cylinder head.

Decarbonizing
Decarbonize the combustion chamber and spark plug hole.
NOTE:
- Take care not to scratch the combustion chamber.
- After decarbonizing, clean it with solvent.

2. Remove the muffler.
3. Remove the cylinder head gasket and remove the cylinder.

NOTE:
Thoroughly remove the gasket from the contact surface of the cylinder with the crankcase.

Checking
1. Check the cylinder wall for scratches. If there is any scratch in the thrust direction, the cylinder should be re bored.
2. Check wear on the cylinder wall.

Measure the cylinder bore diameter in the three depths, A, B and C and in the directions of @ and ⑬. That is, six measurements are necessary. The difference between the maximum and minimum measurements is the amount of wear.

Max. wear: 0.05 mm (0.002 in) or less

When the cylinder is worn more than the above limit, it should be bored or replaced.
Decarbonizing
Decarbonize the cylinder exhaust port.

PISTON AND PISTON RINGS

Removing
1. Remove the cylinder head.
2. Remove the cylinder.
3. Remove the piston pin clips.

NOTE:
Cover the crankcase with a clean cloth to prevent piston pin clips from falling into the case.

4. Pull out the piston pin and remove the small-end bearing.

5. Remove the piston rings from the piston.

NOTE:
Take care not to break piston rings.

CHECKING

Piston
1. Check the piston for scratches or cracks, and service or replace, as required.

Cylinder size
1. Hone cylinder bore using a hone with fine stones. Hone no more than required to remove all wear marks.
2. Using a Cylinder Gauge set to standard bore size, measure the cylinder. Measure front-to-rear and side-to-side at top, center and bottom just above exhaust port. Compare minimum and maximum measurements. If over tolerance and not correctable by honing, rebore to next over-size.
Max. allowable taper \((d - a)\):
0.05 mm (0.0020 in)

Max. allowable out-of-round
\((B - A)\) or \(A - B\):
0.01 mm (0.0004 in)

Wear limit:
56.10 mm (2.21 in)
(at "a" position)

Piston size
Measure the piston outside diameter at its skirt.

NOTE:
The measurement should be made at a point 5 mm above the piston bottom edge.

Min. outside diameter:
48.940 mm (1.93 in)

If the outside diameter measures less than the above limit, replace the piston.

Piston clearance
Compare piston diameter to cylinder bore measurements. Piston maximum diameter (as shown below) subtracted from minimum cylinder diameter \((d - B)\) gives piston clearance. If beyond tolerance, hone cylinder to tolerance or re-bore to next over-size and fit over-size piston.

Standard piston clearance:
0.035 ~ 0.040 mm (0.0014 ~ 0.0016 in)

If the piston clearance measures more than the standard value, replace the piston.
Matching piston and cylinder

1. Indication of cylinder size
   The cylinder size is indicated on the piston skirt.
   Example: 012 . . . . . . . 49.012

2. Indication of piston size
   The piston size is indicated in felt point pen on the piston head. (Only brand-new ones)
   Example: 96 . . . . . . . 48.996

c. Calculation of piston clearance
   Indication on piston skirt . . . . . . . 012
   Indication on piston head . . . . . . . 96
   Piston clearance = Cylinder size − Piston size
   = 49.012 mm − 48.996 mm
   = 0.016 mm
   (1.930 in) (1.929 in)
   (0.0006 in)

NOTE:
The sizes indicated on the cylinder and piston are useable for calculations of the piston clearance only when both cylinder and piston are brand-new. Otherwise, the difference between the cylinder bore and piston outside diameters actually measured is the piston clearance.

Piston ring end gap
Place each piston ring in the cylinder skirt and measure the end gap with a thickness gauge.

<table>
<thead>
<tr>
<th>Piston ring end gap</th>
<th>Top ring</th>
<th>0.15 ~ 0.35 mm (0.006 ~ 0.014 in)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Second ring</td>
<td></td>
</tr>
</tbody>
</table>

If the end gap exceeds the above specification, replace the ring.

NOTE:
Place each piston ring in the cylinder skirt (where the cylinder bore diameter is minimum) and measure the ring end gap.

Piston ring side clearance
Measure the clearance between the ring and groove.

<table>
<thead>
<tr>
<th>Side clearance</th>
<th>Top ring</th>
<th>0.15 ~ 0.35 mm (0.006 ~ 0.014 in)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Second ring</td>
<td></td>
</tr>
</tbody>
</table>

If the side clearance is more than specified, replace the piston ring.
Insert the thickness gauge into the groove so it contacts the bottom of the groove.

2. Check that the piston pin moves into the pin smoothly.

If it is hard to fit in, check the pin hole for scratches or protuberances, and smooth out using a scraper.

CAUTION:
- Before measuring, decarbonize the grooves.
- Make measurements at several points.
- The second ring has an expander. Don’t forget to install the expander.

1. Fit the piston rings in the grooves.
2. Align each ring end gap with the locating pin.

NOTE:
- Take care not to scratch the piston or break the piston rings.
- Make sure all piston rings are fit with markings facing upward.
- Piston rings should be replaced as a set, when replaced.
- After fitting the rings, check that they move smoothly.

Piston
1. Install the piston onto the connecting rod so that the arrow mark on the piston crown faces toward the exhaust port.

2. Install the piston pin clip.

NOTE:
- Apply oil to the connecting rod small-end bearing, piston pin, and piston before installing.
- Take care not to scratch the piston.
- Always use new piston pin clips.

2. While holding down the piston rings, insert the piston into the cylinder.

NOTE:
- Align the piston ring end gaps with the locating pins, and insert the piston into the cylinder.
- Coat the piston, piston rings and cylinder wall with air cooled 2-stroke oil.
- After inserting the piston, make sure that the piston can be moved up and down smoothly.

CHECKING

Sparks
1. Remove side cover 4.
2. Disconnect the spark plug cap from the high-tension wire, and bring the wire end to a point 5 or 6 mm (0.20 or 0.24 in) off the cylinder head or the air shroud.
3. Push the starter switch (or kick the kick-starter), and if spark takes place, the CDI system is considered to be in good condition. (Main switch ........... ON)
NOTE:
Be careful not to touch the high-tension wire.

When spark takes place:
Check plug cap and spark plug.

If no spark takes place:
Check the CDI parts.

Couplers and connectors
1. Check couplers and connectors for loose connections.
2. Check for dirt and rust.

CDI magneto
Measure the resistance of the CDI magneto pick-up and charge coils.
1. Remove side cover 2 and disconnect the CDI magneto coupler.
2. Using the Pocket Tester, measure the resistance.

If the resistance measured shows a big difference, replace the ignition coil.

IGNITION COIL

Primary winding resistance
1. Remove side covers 2 and 4 and remove the ignition coil connector.
2. Using the Pocket Tester, measure the resistance.

</tr>
</thead>
<tbody>
<tr>
<td>Primary winding</td>

</tr>
</tbody>
</table>

If the resistance measured shows a big difference, replace the ignition coil.
Secondary winding resistance
Remove the spark plug cap and using the pocket Tester, measure the resistance of the secondary winding.

If the resistance measured shows a big difference, replace the ignition coil.

Ignition coil
Remove the ignition coil from the engine and connect it to the Coil Tester. Make a spark test for more than five minutes.

If spark takes place irregularly or will not take place at all, the ignition coil should be replaced.

NOTE:
The Coil Tester knob should be set 0 or thereabout first, and then it should be turned in steps.

CDI UNIT
1. Remove side cover 3.
2. Check that the connector and coupler are plugged in lightly.
3. Check the connector and coupler for dirt or rust.

NOTE:
- When disconnecting the connector or coupler, hold its body. Don’t pull the wire.
- Make sure the CDI unit is wired correctly, since a large amount of current flows from the CDI unit to the ignition coil.

4. If no spark will take place even when the CDI magneto wiring, coupler, ignition coil and spark plug all are in good condition, make a check by replacing the CDI unit with a new one.
STARTER SYSTEM

6-7
TERMINALS AND WIRING
1. Check the terminals of the battery, starter switch, and starter motor for loose connections.
2. Check the wire harness for broken wires.

BATTERY

Removing
1. Remove side cover 2.
2. Remove the plate and disconnect both positive and negative wires, and breather pipe.

3. Remove the battery.

Checking
1. Remove the cap of each cell and measure the specific gravity of battery fluid.

Specific gravity:
1.250 ~ 1.280 [at 20°C (68°F)]

2. The specific gravity decreases with a decrease in the charge of the battery. In other words, the specific gravity represents the state of charge of the battery. When the specific gravity of a fully-charged battery is 1.280 [at 20°C (68°F)], the specific gravity varies with the state of charge as shown in the following table:

<table>
<thead>
<tr>
<th>State of discharge of the battery (%)</th>

</tr>
<tr>

</tr>
<tr>

<td>1.040</td>
</tr>
</tbody>
</table>

3. Check the battery fluid level. If the fluid level is lower than the lower level line, add distilled water.

1. Upper level 2. Lower level
Mounting the battery
1. Place the battery in the battery box and install the plate.
2. Connect the breather pipe and connect the positive and negative wires to the battery.

CAUTION:
- Connect the positive wire first.
- Make sure the battery breather pipe is firmly connected and that it is not kinked or flattened.
- Make sure there is no slack in the lead wire connecting the starter switch to the battery positive terminal and in the ground wire (between the starter switch and engine). If the slack is excessive, lead wires may contact the rear suspension.

3. Install side cover 2.

STARTER SWITCH CHECKING

Leads continuity
1. Remove the headlight unit and make a continuity test using the Pocket Tester.

<table>

</tr>
<tr>

</tr>
</tbody>
</table>

2. If there is no continuity, the starter switch is faulty.

Primary winding
1. Remove side cover 2.
2. Disconnect the starter switch coupler, remove the starter switch, and make a continuity test using the Pocket Tester.

<table>
<thead>
<tr>

<td></td>
<td>R x 1</td>
</tr>
</tbody>
</table>

If there is no continuity, the starter switch is faulty.
Secondary terminals
1. Connect the positive side of the 6V battery to the Black/Yellow lead wire of the starter switch, and connect the negative side to the Blue/White lead wire.
2. Using the Pocket Tester, check continuity between the secondary terminals (Red – Black).

If there is not continuity, the starter switch is faulty.

STARTER MOTOR
1. Remove the starter clutch assembly.

1. Starter clutch ass'y

NOTE:
When removing the starter clutch assembly, the roller, compression spring and starter clutch spring cap tend to fall off. So remove it carefully.

2. Remove the starter motor screw and remove the starter motor and starter wheel from the crankcase.

3. Disconnect the lead wire from the starter motor.

CHECKING

Brushes
1. Remove the case mounting bolts.
2. Check the length of each brush.
<table>
<thead>
<tr>
<th></th>
<th>Standard</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brush length</td>
<td>11 mm (0.4 in)</td>
<td>5 mm (0.2 in)</td>
</tr>
</tbody>
</table>

If the length is shorter than the limit, replace the brush.

3. Check spring tension.

<table>
<thead>
<tr>
<th></th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spring tension</td>
<td>300 g (10.6 oz) or less</td>
</tr>
</tbody>
</table>

If the length is shorter than the limit, replace the brush.

**Commutator**
1. Replace the commutator if it has serious scratches or damage.
2. Check the outside diameter of the commutator.

3. Check the commutator for scratches, grooved wear, or burning. If necessary, grip the armature in a vise and smooth out using a sandpaper (#500 ~ 600).

**NOTE:**
Sand the commutator outer surface lightly and evenly.

**Mica insulation**
After sanding the commutator, check the depth of mica undercuts. If the depth is less than limits, undercut the mica with a hacksaw blade.
After undercutting, chamfer all the edges of segments lightly with sandpaper.
If there is no continuity, repair or replace the armature.

**Starting motor gear**
Check the starter motor gear for breaks or uneven wear.

Replace it if broken or worn unevenly. Also check the armature.

**Assembling and installing**
1. Align the marks on the case and cover and put them together.

**NOTE:**
After assembling, check that the armature turns smoothly.
8.5 Nm (0.85 m·kg, 6 ft·lb)
CHECKING

Coupler and wiring
1. Check that the coupler is connected tightly.
2. Check the coupler for fouling or rust.
3. Check the wire harness for broken wires.

If the coupler is loosely connected, fouled, rusty or has broken wires, recondition or replace it.

Fuse
1. Remove side cover 2.
2. Remove the fuse holder from the fuse box above the battery, and check for continuity.

If there is no continuity, or the socket is loose or damaged, replace the fuse holder.

Charging current
1. Remove side cover 2 and disconnect the fuse connector.
2. Connect the engine tachometer and start the engine.
3. Disconnect the red wire connection at the battery and connect Pocket Tester. Take amperage readings at specified speed.
Rectifier

1. Remove the side cover 2, and disconnect the rectifier coupler.
2. Connect the pocket tester leads as shown.
3. Change the connection, and check the movement of the meter needle.

GENERAL TORQUE SPECIFICATIONS
This chart specifies torque for standard fasteners with standard I.S.O. pitch threads. Torque specifications for special components or assemblies are included in the applicable sections of this book. To avoid warpage, tighten multi-fastener assemblies in a crisscross fashion, in progressive stages, until full torque is reached. Unless otherwise specified, torque specifications call for clean, dry threads. Components should be at room temperature.

#### Consumer Information

**STOPPING DISTANCE**

This figure indicates braking performance that can be met or exceeded by the vehicles to which it applies, without locking the wheels, under different conditions of loading and with partial failures of the braking system. The information presented represents results obtainable by skilled drivers under controlled road and vehicle conditions and the information may not be correct under other conditions.

Sheave surfaces, clutch housing inner surfaces and lining outer surfaces should be free from oil films. Wipe off any oil film with a cloth damp with a lacquer thinner.

Before installing the secondary sheave complete, apply grease to both internal and external spines so that the slots are packed with grease.

Before installing the case cover, oil the drive axle.

When assembling, oil the outer surface of housing boss.

Oil the entire surface of piston lands.

Using an oiler, feed oil into holes.

Apply grease.

No grease is required.

Clip should begin to slip at a load of 200 - 400 g (7.0 - 14 oz) at A.

Apply grease, particularly to gear, worm wheel and its vicinity.

Set conical washer with larger side facing upward.

Threads should be free from grease.

Before installing primary drive gear, oil the drive axle.

Grease needle bearing

Before installing, oil the drive axle.
